

This project will utilize the sample scenario provided, regarding an e-commerce system. Since I am submitting individually, I only intend to use 4 tables; as such, I will be modifying the “multiple credit cards” version of the scenario to have users only use one credit card, which may be null.

The system requires two main user roles, being Users and staff. The business logic requirement will be addressed by writing simple html pages (accessed on localhost, in this case) and using these pages to fulfill the expected capabilities of each (viewing products, removing products, etc.)

The following are relational schema based on the ER diagram I made for this system, primary keys are indicated with *italics*:

Strong entities:

Customer(*CID*, Name, Password, Credit Card #)

Staff (*SID*, Name, Password)

Product(*PID*, Name, Type*, price, current stock)

*Type refers to a broad category of sold items from the site; for example there might be an “apparel” type for clothes or a “Hygiene” type for toothpaste and shampoo, etc.

Relationship:

Purchases(*Purchase #*, CID, PID, Date, Quantity Bought, total price)
